

Innovationer för hållbar växtodling

3d. Underlag för ett webbaserat beslutsstödssystem för precisionsodling

Lena Engström, Kristin Piikki, Mats Söderström och Bo Stenberg.

Sveriges lantbruksuniversitet (**SLU**) , Inst. för Mark och miljö,
Precisionsodling och pedometri, Skara, **Sverige**.

3d. Underlag för ett webbaserat beslutsstödssystem för precisionsodling

Syfte och mål med delaktiviteten:

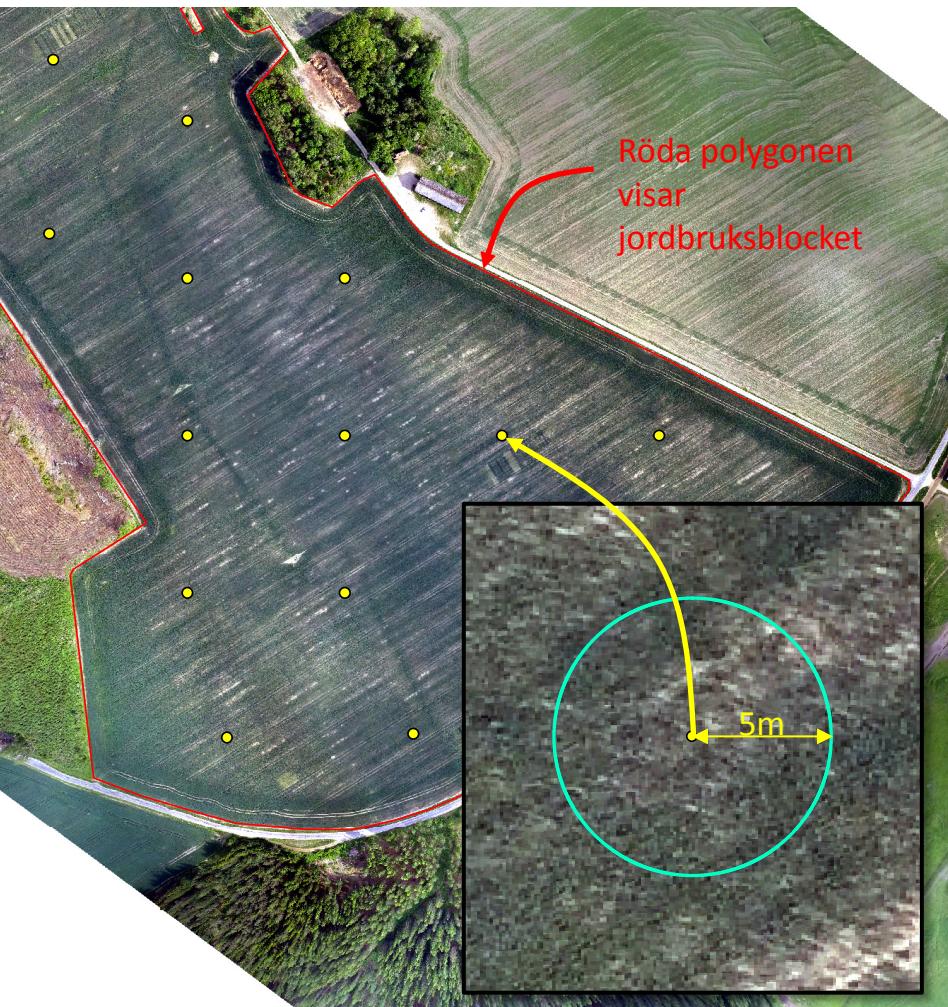

utveckla och anpassa algoritmer som översätter tillgängliga
gröd- och markdata till platsanpassade åtgärdsrekommendationer.

3d. Underlag för ett webbaserat beslutsstödssystem för precisionsodling

Med hjälp av olika verktyg som handburna sensorer, drönare och satelliter:

- I höstvete bestämma **skörd** vid kompletterings gödsling.
- I höstraps bestämma **kväveinnehåll på hösten** för optimal beräkning av vårgivan.
- I gräsvall bestämma **näringsinnehåll** för optimal **skördetidsprognos**.

Data från drönare:

Fotografering med RGB-kamera
 (RX-100, Sony)

Fotografering med multispectral kamera
 (RedEdge, Micasense)

Skapande av mosaik
 (SOLVI)

Skapande av mosaik
 (Micasense ATLAS)

Georeferering

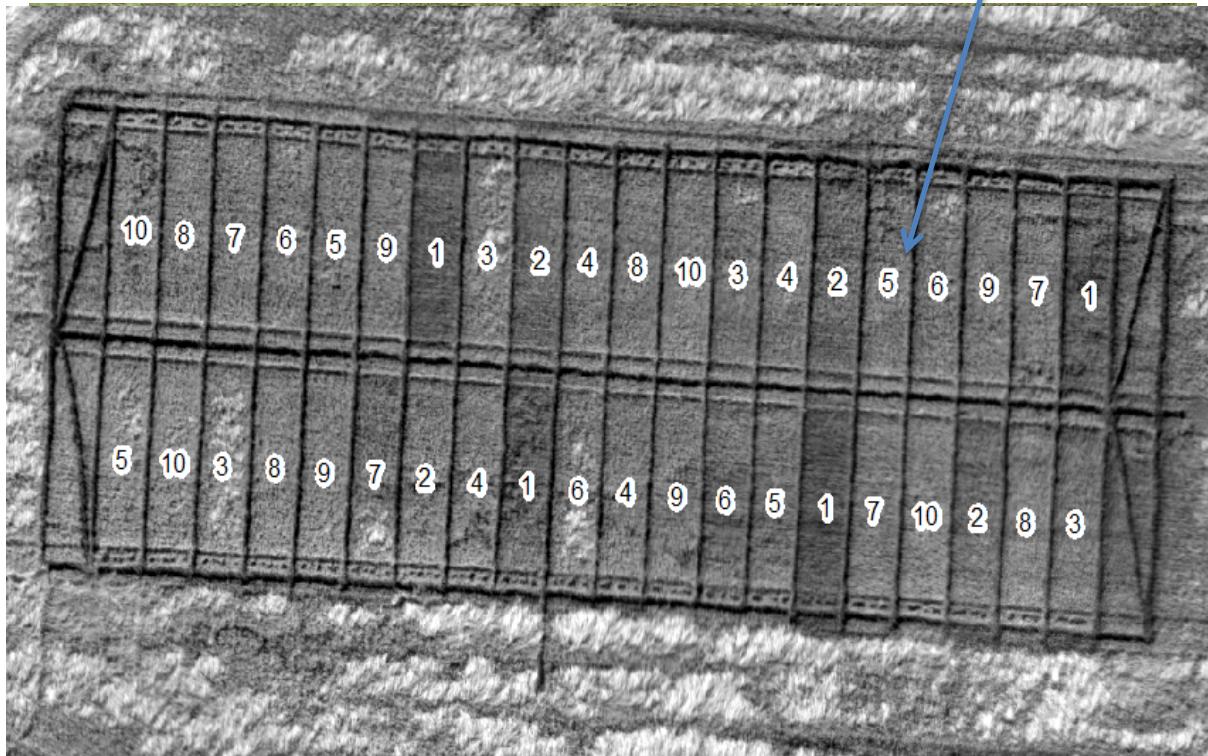

Mosaikerna georefererades med hjälp av Jordbruksverkets blockdatabas. Ofta 5-10 m fel innan georeferering. (ArcGIS, ESRI).

Dataextraktion

Ett medelvärde för alla celler inom 5 m radie från inmätta punkten beräknades. Detta gjordes band för band (www.r-project.org).

Data från drönare i försök:

Mosaikbildens pixlar 8 x 8 cm, medianvärdet i varje ruta tas fram för de fem våglängdsbanden

Data från satelliter:

- 10x10, 20x20, 30x30 m raster/pixel = 1 värde

Winter oilseed rape

Decision support for calculating the optimal N rate in spring to winter oilseed rape by estimation of N-uptake in autumn by means of remote sensing.

Four fields, crop sampling (1 m^2) at five positions in each field in late autumn, n= 25.

RGB-image 13/10 2016, Entorp, Skara, 22 – 144 kg N/ha

Innovationer för
hållbar växtodling

Winter oilseed rape

Lanna, skifte 13, 12 – 84 kg N/ha

Winter oilseed rape

Bjertorp skifte 31, 48 – 145 kg N/ha

hållbar växtodling

Results 2016:

Modelling the autumn N-uptake of winter oilseed

- Best prediction of N-uptake (11-90 kg N/ha, 4 sites, n= 20) with **RGB-pictures** (drone) and handheld **GreenSeeker** (NDVI), RMSECV = **12 kg N/ha**.
- Good prediction models also with **all wavebands** (RMSEC = 14 kg N/ha) or single indices, RMSECV = **15-16 kg N/ha** (drone).
- No good prediction with satellite-pictures since sampling area (1 m^2) did not properly represent the area of 10 - 30 m pixels in the satellites.

Regression models (PLS and SLR)

Response:

N-uptake (kg N/ha).

Predictors:

All wave bands (B, G, R, Rededge, NIR)

Indices (NDVI, MSAVI, SAVI)

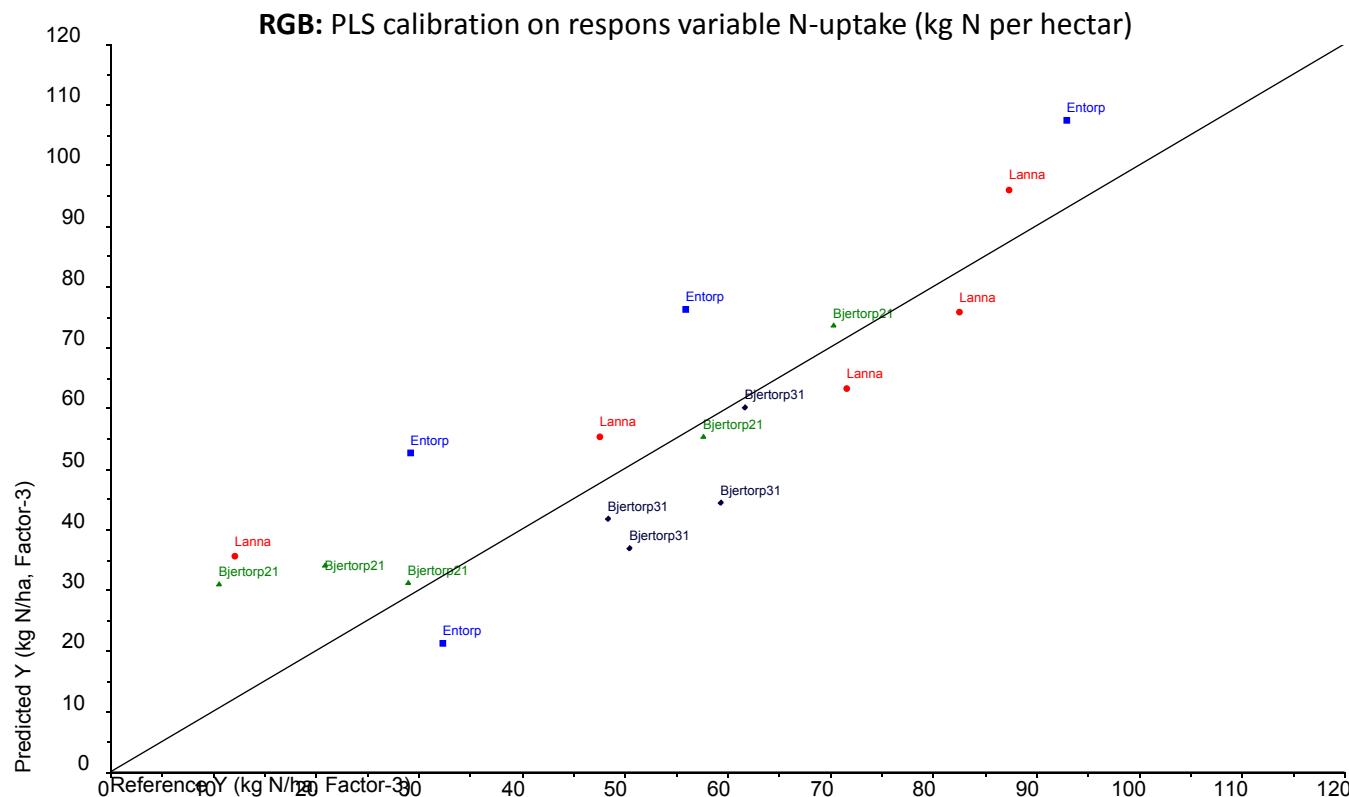

RGB

Regression models		Cross-validated		
		r ²	RMSECV	rpd
UAV- Micasense, indices				
NDVI	all	0,38	33	1,2
	not 2 high	0,64	15	1,6
	val. gårdar	0,58	16	1,5

not Entorp	all	0,24	37	1,0
	ej 2 höga	0,69	14	1,7
	val. fields	0,30	21	1,1
UAV – Sony (R, G, B)				
	all	0,16	38	1,1
	not 2 high	0,77	12	2,1
	val. fields	0,71	13	1,9
Handheld GreenSeeker				
NDVI	all	0,57	28	1,5
	Not 2 high	0,78	12	2,1
	val. fields	0,68	14	1,8

Results:

UAV - Sony (R,G, B)

Cross validated model (4 sites), $R^2 = 0,71$, RMSECV = 13

Plans for 2017:

- 50-70 crop samples at 4-6 sites 2017
- 10-20 samples with high biomass, 100-200 kg N/ha.
- Improve georeferencing by using 2- 3 markers around each sampling plot, instead of only one (2016).
- Adapt sampling strategi for satellite pictures.
Sample in larger homogenous areas!

Results 2016:

Modelling yield in winter winter wheat

- **Using 6 fields with 20 samples in each (n= 120):**

No good prediction of yield (or N-uptake and biomass) was achieved with the models tested (multispectral images from drones and satellites).

- No good prediction due to sampling area (0,5 x 0,5 m) did not properly represent the area from the satellite and UAV pictures.

- **Using 4 field trials from 2015 (n= 225) and a handheld sensor (multispectral):**

Good prediction of yield was achieved with all wavebands, NDVI+Rededge and MSAVI+Rededge.

n= 225	Korsvalidering			Validering gårdsvis

Skofteby 2017

All wave bands and cross validation with N-treatments (16)

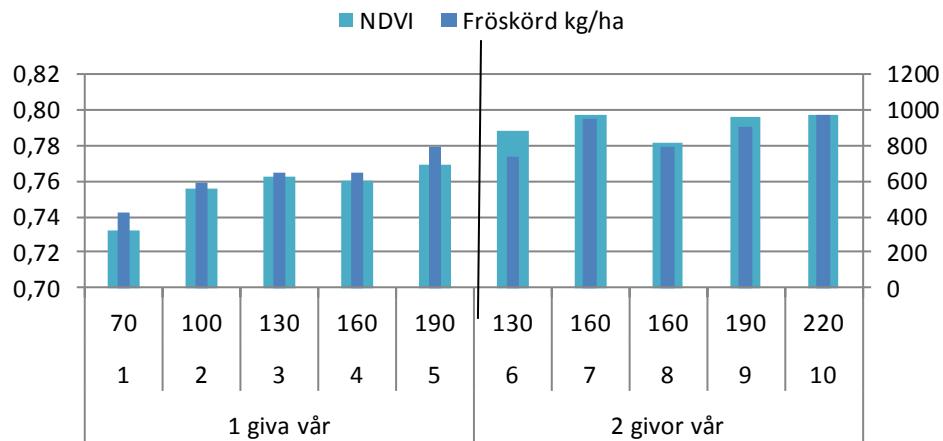

Results 2016:

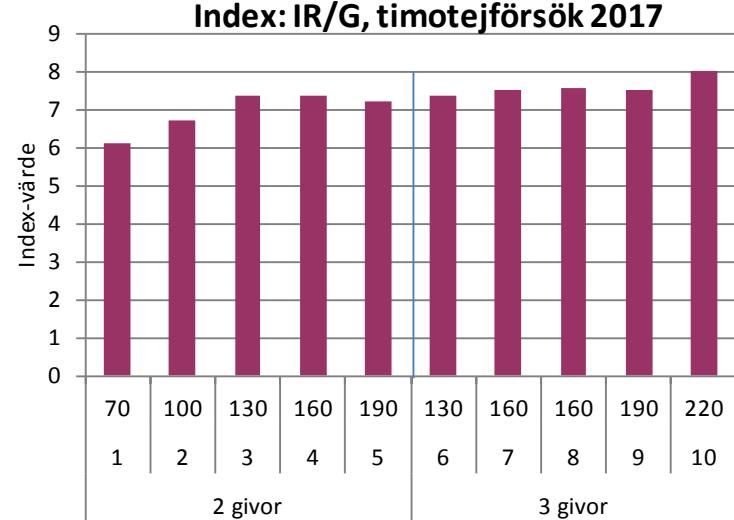

Modelling protein, energy and NDF in timothy grass leys

- No good regression models could be made when using UAV-pictures from 3 fields with 5 samples in each at 3 harvest dates, n= 45 or a field experiment (n= 70). Satellite pictures not analyzed yet.
- Visual differences between treatments in field trials were well described by e.g. NDVI 8/7 2016 (UAV) and IR/R och Si1 15/6 2017 (handheld N-sensor)!

NDVI, timotej-försök 2016

Index: IR/G, timotejförsök 2017

Results 2017:

Modelling protein, energy and NDF in timothy grass leys

- Using a field trial in a timothy grassley with increasing N-rates ($n= 40$) and crop sampling at three harvest dates (15/6, 27/6, 10/7, $n=120$).
- Good prediction of yield was achieved with all wavebands, RGB, the indices GNDVI and ChII (two dates $n= 80$)
- The results from the third harvest date have not yet been analysed.

Regression models (PLS and SLR)

Response:

Yield (kg/ha)

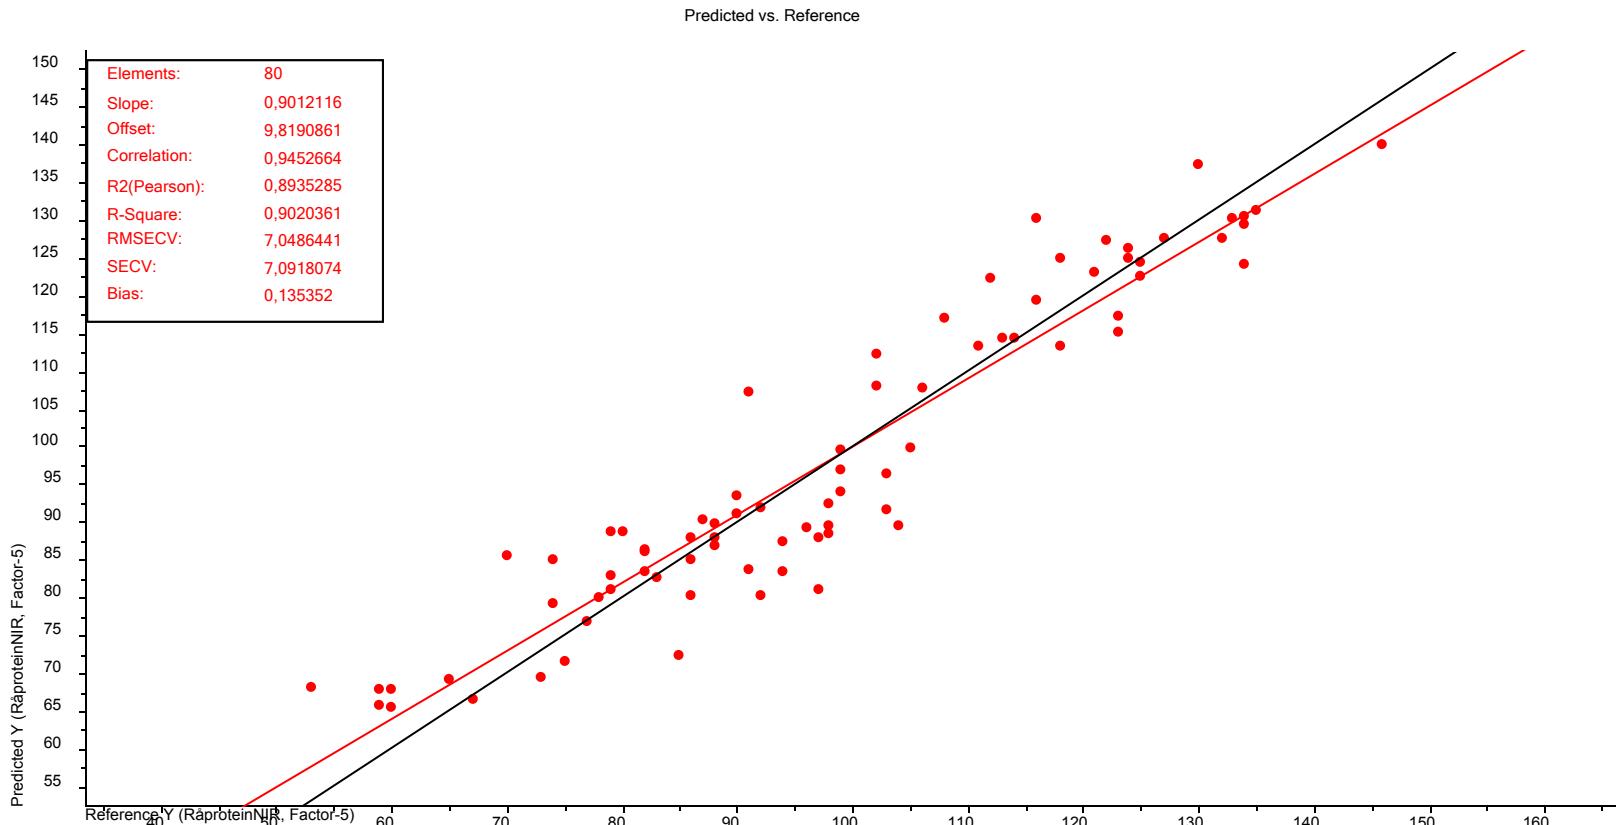

Predictors:

5 wave bands (B,G,R, Rededge, NIR)

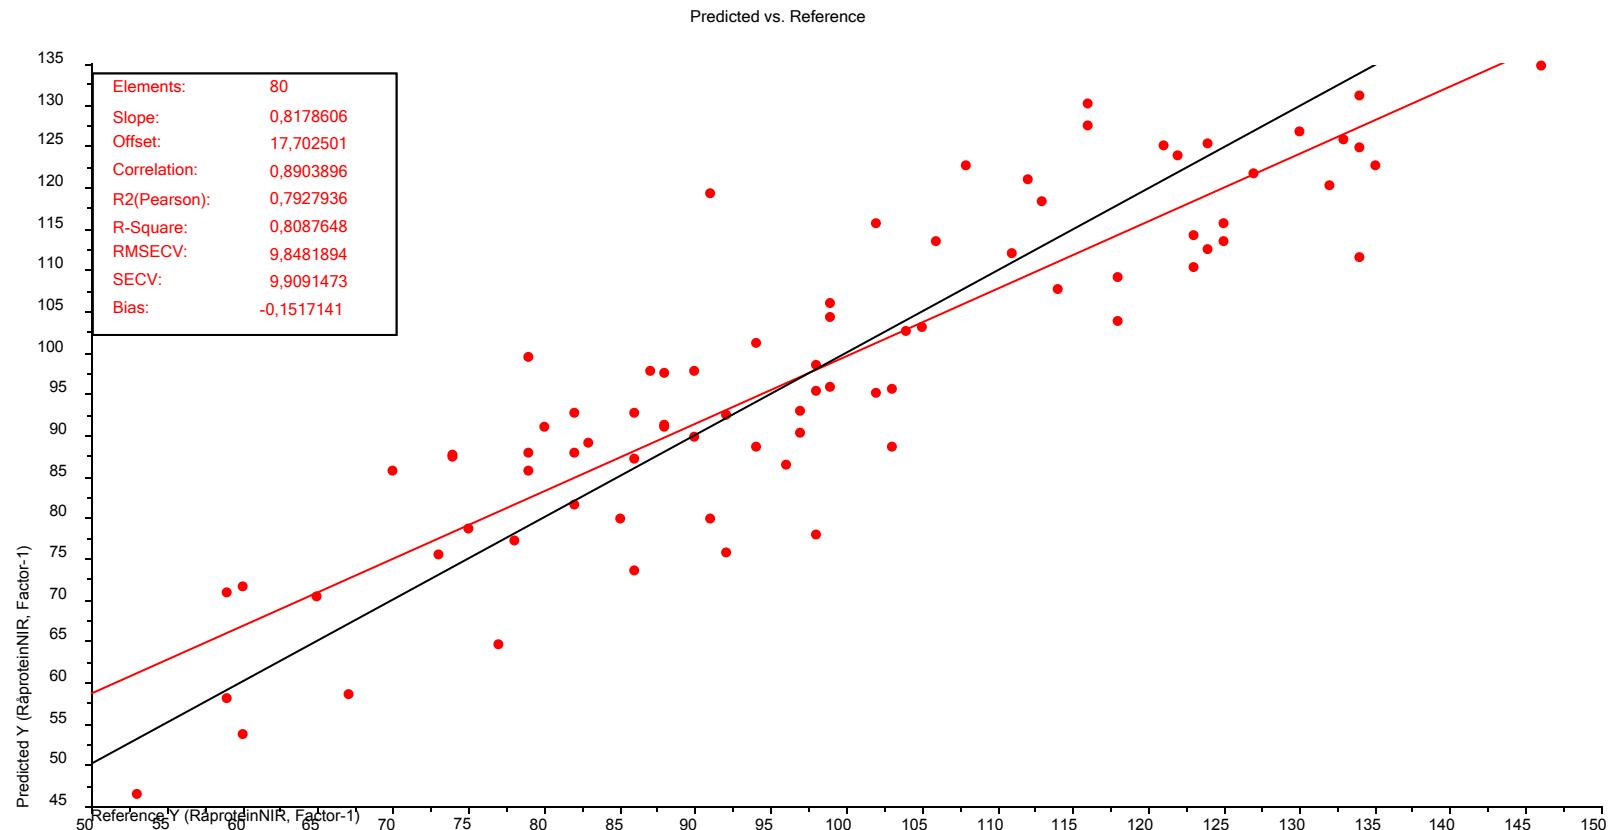

Indices (GNDVI, ChII)
